In a prospective randomized multicenter study on the usefulness of diclofenac suppositories for pain relief of women with lower abdominal pain, 559 women were treated. The suppositories were administered in daily doses of 50 mg up to a maximum of 400 mg per 24 hours (200 mg three times daily). The efficacy of the suppositories was assessed using a visual analog scale (VAS) and a questionnaire which covered the condition of the abdominal organs in addition to the level of pain. On day 0, the mean VAS was 3.07 +/- 0.95, and on day 5, it was 1.48 +/- 0.95. On day 5, the mean score was significantly lower than on day 0 (P less than 0.001). Improvements were not dependent upon the intensity of pain. The evaluation of the abdominal condition on day 5 revealed relief of constipation in 63.7% of patients. The effective treatment of constipation was scored by women as a very important factor in the relief of their abdominal pain. A significantly greater number of patients had improved in the absence of an underlying organic disease than in its presence (P less than 0.01). The suppositories were well tolerated.Without limiting the scope of the invention, its background is described in connection with polyurethane polymers and, more particularly, with the reaction of polyisocyanates and water. Conventional polyurethane polymers are currently prepared from polyether polyols, which are generally prepared by the reaction of alkylene oxides with water. The reaction is controlled so as to produce a polyether polyol having a narrow molecular weight distribution and a substantially linear structure, and terminated with hydroxyl groups. The functionality of the polyether polyol is generally greater than one, in order to allow crosslinking reactions to occur, for example by reaction with isocyanates. The polyurethane polymers are typically prepared by reacting a polyisocyanate and the polyether polyol in the presence of a catalyst and a blowing agent. Typically, the polyether polyol is a mono- or polyfunctional compound, and the polyisocyanate is an aliphatic or aromatic compound having a functionality greater than one. The polyurethane polymers are referred to as polyurethane polymers, and compositions based on polyurethane polymers are generally referred to as polyurethane compositions. The polyether polyols that are used to prepare polyurethane polymers are generally expensive to produce and use.
